Abstract

We examine the decays $t \rightarrow c\gamma$ and cZ^0 in the Standard Model with an extra scalar doublet and no discrete symmetry preventing tree-level flavour changing neutral currents. The Yukawa couplings of the new scalars are assumed to be proportional to fermion masses, evading bounds on FCNC's from the light quark sector. These rare top decays may be visible at the SSC.

Flavour changing neutral currents (FCNC's) involving the light quarks are known experimentally to be strongly suppressed, placing stringent bounds on the nature of new flavour physics. The gauge interaction of the fermions in the standard model has a global $[U(3)]^5$ flavour symmetry; this is broken to $[U(1)]^4$ by the Higgs Yukawa couplings, and the flavour symmetries are broken most strongly for the heavier quarks. If the observed pattern of masses and mixing angles reflects an underlying pattern of symmetry breaking, it is natural to expect that new flavour physics will also respect this pattern of symmetry breaking. Hence, it would couple most strongly to the top quark, for which the flavour symmetry is most strongly broken, while coupling only very weakly to the light fermions. This may allow the scale of new flavour physics to be as low as the weak scale without contradicting current experimental limits on FCNC's for light quarks.

A simple example is the Standard Model with extra scalars. These new scalars will typically have tree-level flavour-changing Yukawa couplings. However, as has been discussed by several authors [1]–[5], if the Yukawa couplings of the extra scalars are proportional to the fermion masses, low energy limits on FCNC's may be evaded because the flavour changing couplings to the light quarks are small. The discrete symmetries which are normally invoked in two-Higgs doublet models to forbid tree level FCNC's [6] are therefore unnecessary. It has been suggested that these FCNC's may be looked for in b decays, and in particular the leptonic decay $B_s \rightarrow \mu^+ \mu^-$ may be observable at hadron colliders [2][5].

If this philosophy is correct, one would expect to see the largest effects of these FCNC's in t decays. The resulting rare t decays may be searched for at the SSC, where $\sim 10^8$ $t\bar{t}$ pairs are expected to be produced per year. FCNC's of gauge bosons in both the standard model [7]–[12] and in two-Higgs doublet models with discrete symmetries [13]–[15] have been studied extensively in the past. In the Standard Model and two-Higgs doublet models (with ratios of Higgs vevs of order one) the branching ratios for $t \rightarrow cZ^0$ and $t \rightarrow c\gamma$ are less than $O(10^{-11})$ [16] [17] and so would be unobservable at the SSC. In this paper we will calculate the rates for $t \rightarrow c\gamma$ and $t \rightarrow cZ^0$ in the Standard Model with an extra scalar doublet, but without the discrete symmetries which prevent tree-level FCNC's in two-Higgs doublet models.[†] We will not discuss the decay $t \rightarrow cg$ as the multi-jet background from the primary decay mode $t \rightarrow bW^+$ will make this mode unobservable. We will assume that the new scalars are heavier than the top; the case of $m_h < m_t$ has been considered in [3], as has the tree-level decay $h \rightarrow \bar{t}c$ for $m_h > m_t$. We note that the latter process

[†] The mode $t \rightarrow c\gamma$ has also been recently discussed in [18].

($h \rightarrow W + \text{jets}$) has no clear signature and will be very difficult to see at the SSC; in this case loop effects such as those described here may be the only way to see these couplings at a hadron collider.

We consider a model with two scalar $SU(2)_W$ doublets, φ_1 and φ_2 :

$$\varphi_1 = \begin{pmatrix} \varphi_1^+ \\ \varphi_1^0 \end{pmatrix}, \quad \varphi_2 = \begin{pmatrix} \varphi_2^+ \\ \varphi_2^0 \end{pmatrix} \quad (1)$$

with Lagrangian

$$\mathcal{L}_\varphi = D^\mu \varphi_1^\dagger D_\mu \varphi_1 + D^\mu \varphi_2^\dagger D_\mu \varphi_2 - V(\varphi_1, \varphi_2) \quad (2)$$

where $V(\varphi_1, \varphi_2)$ is the most general potential consistent with the gauge symmetries. Since there is no global symmetry which distinguishes the two doublets we may work in a basis where only φ_1 has a VEV without loss of generality:

$$\langle \varphi_1 \rangle = \begin{pmatrix} 0 \\ v/\sqrt{2} \end{pmatrix}, \quad \langle \varphi_2 \rangle = 0 \quad (3)$$

where $v = 246$ GeV. Three of the components of φ_1 become the longitudinal components of the $W^\pm$ and Z^0 , while the spectrum contains the charged scalars $\varphi_2^\pm$, the neutral scalars h^0 and H^0 and the pseudoscalar A^0 , where

$$\begin{aligned} H^0 &= \sqrt{2} [(\text{Re } \varphi_1^0 - v) \cos \alpha + \text{Re } \varphi_2^0 \sin \alpha], \\ h^0 &= \sqrt{2} [-(\text{Re } \varphi_1^0 - v) \sin \alpha + \text{Re } \varphi_2^0 \cos \alpha], \\ A^0 &= \sqrt{2} [-\text{Im } \varphi_2^0]. \end{aligned} \quad (4)$$

The mixing angle α is determined by the potential and is a free parameter of the model, as are the masses $m_{\varphi_2^\pm}$, m_h , m_H and m_A . The Yukawa couplings to fermions are

$$\begin{aligned} \mathcal{L}_Y &= \lambda_{ij}^U \bar{Q}_i \tilde{\varphi}_1 U_j + \lambda_{ij}^D \bar{Q}_i \varphi_1 D_j + \lambda_{ij}^E \bar{L}_i \varphi_1 E_j \\ &+ \xi_{ij}^U \bar{Q}_i \tilde{\varphi}_2 U_j + \xi_{ij}^D \bar{Q}_i \varphi_2 D_j + \xi_{ij}^E \bar{L}_i \varphi_2 E_j \end{aligned} \quad (5)$$

where $\tilde{\varphi}_{1,2} \equiv i\tau_2 \varphi_{1,2}^*$. With the usual manipulations we write λ^U , λ^D and λ^E in terms of the mass matrices $\sqrt{2} M^U/v$, $\sqrt{2} M^D V^\dagger/v$ and $\sqrt{2} M^E/v$, where V is the Kobayashi-Maskawa (KM) matrix. We have used all our freedom to redefine the fermion fields to diagonalise M_U , $M_D V^\dagger$ and M_E , so the matrices $\xi^{U,D,E}$ are general 3×3 matrices:

$$\begin{aligned} \xi^U &= \begin{pmatrix} \xi_{uu} & \xi_{uc} & \xi_{ut} \\ \xi_{cu} & \xi_{cc} & \xi_{ct} \\ \xi_{tu} & \xi_{tc} & \xi_{tt} \end{pmatrix} & \xi^D &= \begin{pmatrix} \xi_{dd} & \xi_{ds} & \xi_{db} \\ \xi_{sd} & \xi_{ss} & \xi_{sb} \\ \xi_{bd} & \xi_{bs} & \xi_{bb} \end{pmatrix} \\ \xi^E &= \begin{pmatrix} \xi_{ee} & \xi_{e\mu} & \xi_{e\tau} \\ \xi_{\mu e} & \xi_{\mu\mu} & \xi_{\mu\tau} \\ \xi_{\tau e} & \xi_{\tau\mu} & \xi_{\tau\tau} \end{pmatrix}. \end{aligned} \quad (6)$$

A priori, the ξ 's are all free parameters, and are constrained in the light quark sector from the lack of observation of FCNC's. Two possible forms for the scalar couplings, motivated by the observed structures of the KM and fermion mass matrices, are the Cheng-Sher (CS) ansatz [1]

$$\xi_{ij} \sim \frac{\sqrt{m_i m_j}}{v} \quad (7)$$

and the Antaramian, Hall and Rasin (AHR) ansatz (for Higgs vevs $v_1 = v_2 = v$) [5]

$$\begin{aligned} \xi_{ij}^U &\sim \frac{m_{U_j}}{v} \left(\frac{m_{U_i} m_{D_i}}{m_{U_j} m_{D_j}} \right)^{1/4} \\ \xi_{ij}^D &\sim \frac{m_{D_j}}{v} \left(\frac{m_{U_i} m_{D_i}}{m_{U_j} m_{D_j}} \right)^{1/4} \\ \xi_{ij}^E &\sim \frac{\sqrt{m_{E_i} m_{E_j}}}{v}. \end{aligned} \quad (8)$$

In this work we will not make a specific ansatz for the ξ 's but will simply assume that they are roughly proportional to powers of quark masses, allowing us to retain only ξ_{tt} and the flavour changing couplings ξ_{tc} and ξ_{ct} . In general the ξ 's will also be complex, introducing additional CP violation into the theory; this will not be important for our results.

The general form of the amplitude $\mathcal{A}(t \rightarrow c + V)$ where $V = \gamma$ or Z^0 is

$$\mathcal{A} = \frac{1}{16\pi^2} \bar{u}_c \left(A \gamma^\mu + B \gamma^\mu \gamma_5 + iC \sigma^{\mu\nu} \frac{q_\nu}{m_t} + iD \sigma^{\mu\nu} \gamma_5 \frac{q_\nu}{m_t} \right) u_t \epsilon_\mu, \quad (9)$$

where $\bar{u}_t$, u_c and ϵ_μ are the incoming and outgoing spinors and the gauge boson polarisation vector respectively. The coefficient functions A, B, C and D are computed from the diagrams in fig. 1. There are contributions from both neutral and charged scalars in the intermediate states; note that the charged scalar couplings are not proportional to the KM matrix in this model. The expressions for the coefficient functions are lengthy and are given in the Appendix. For the photon, electromagnetic gauge invariance implies that the vector and axial vector form factors A and B vanish. In terms of the coefficient functions the decay widths are

$$\begin{aligned} \Gamma(t \rightarrow c\gamma) &= \frac{1}{8\pi} m_t (|C|^2 + |D|^2) \\ \Gamma(t \rightarrow cZ^0) &= \frac{1}{16\pi m_t} \left(1 - \frac{m_Z^2}{m_t^2} \right) \left(\frac{m_t^2}{m_Z^2} - 1 \right) \left[(m_t^2 + 2m_Z^2)(|A|^2 + |B|^2) \right. \\ &\quad \left. - 6m_Z^2 \text{Re}(A^* C - B^* D) + m_Z^2 \left(\frac{m_Z^2}{m_t^2} + 2 \right) (|C|^2 + |D|^2) \right] \end{aligned} \quad (10)$$

from which we compute the branching fraction by normalising to the rate for $t \rightarrow bW$

$$\Gamma(t \rightarrow bW) = \frac{G_F}{8\pi\sqrt{2}} |V_{bt}|^2 m_t^3 \left(1 - \frac{m_W^2}{m_t^2}\right) \left(1 + \frac{m_W^2}{m_t^2} - 2\frac{m_W^4}{m_t^4}\right). \quad (11)$$

To avoid an excess of free parameters, we have plotted the branching ratios as a function of a common scalar mass, $m_{\varphi_2^\pm} = m_h = m_H = m_A \equiv M$ in fig. 2. We have also set the flavour changing couplings of the charged scalars, neutral scalars and pseudoscalar to be equal to a generic coupling constant $\bar{\xi}_{tc}$, where $\bar{\xi}_{tc} \sim \xi_{tc} \sim \xi_{ct} \sim (\xi_{tc} \pm \xi_{ct})/2$. These simplifications do not qualitatively change our results. We have multiplied our branching fraction to Z^0 's by the 6.7% branching fraction for $Z^0 \rightarrow e^+e^- + \mu^+\mu^-$ [19], as the hadronic decays of the Z^0 have an insurmountable background from the dominant two-body decay of the top $t \rightarrow bW \rightarrow b + \text{hadrons}$.

For an ansatz of the form (7) we expect $(\xi_{tt}\bar{\xi}_{tc})^2 \sim m_t^3 m_c / v^4 \sim 10^{-3}$. The more complicated ansatz (8) gives a similar estimate. Given the expected $\sim 10^8 \bar{t}t$ pairs expected per year at the SSC, this corresponds, for light scalars with masses of order the t quark mass, to at best only a few events per year in the photon channel. For larger couplings, the expected signal of course dramatically improves.

It is useful to examine our results in the context of other limits on the scalar masses which have been discussed in the literature. The most stringent limits come from $\bar{B}^0 - B^0$ and $\bar{K}^0 - K^0$ mixing. For the AHR ansatz (8), these give lower limits $M \gtrsim 400$ GeV and $M \gtrsim 500$ GeV respectively[5]. In a recent work [4], Chang, Hou and Keung have calculated the two-loop contributions to $\mu \rightarrow e\gamma$ using the CS ansatz (7). From the current upper limits on this decay mode they placed a lower bound of $M \gtrsim 200$ GeV. Other processes place lower limits on M which are less than the t quark mass and hence do not constrain our results. It is important to note, as pointed out in [2] and [4], that these constraints arise from couplings to the down-type quark and lepton sectors only. It is conceivable that flavour changing couplings are large only in the up-type quark sector, for which the constraints on M are much weaker. The possibility of $M \sim m_t$ with large flavour changing couplings in the up sector is not excluded. In the absence of any compelling theoretical reason to prefer a particular choice of ξ^U 's we feel it is best to simply regard them as free parameters to be measured or constrained at the SSC.

In conclusion, we have calculated the branching ratios for $t \rightarrow c\gamma$ and $t \rightarrow cZ^0$ in the Standard Model with an extra scalar doublet, but without discrete symmetries preventing tree-level FCNC's. For flavour changing couplings suggested by simple ansatzes

for the Yukawa couplings these decay modes would not be observable at the SSC, given the constraints on the scalar masses from other processes. However, these constraints may be evaded if flavour changing couplings are larger in the u quark sector than for the d quark and lepton sectors. In this case, the flavour changing couplings and scalar masses are virtually unconstrained. Consequently, sizeable branching ratios for $t \rightarrow c\gamma$ and $t \rightarrow cZ^0$ are possible. To determine whether or not these decays are observable at the SSC requires a thorough background study; we have not attempted this in this work.

We wish to thank Ann Nelson and David Kaplan for numerous discussions. This work was supported in part by DOE grant DE-FG03-90ER40546 and by National Science Foundation Grant PHY-8958081. Appendix A. Expressions for the Coefficient Functions

For simplicity, we set the mixing angle α to zero; the flavour changing couplings then only involve φ_2 . We split each coefficient up into contributions from graphs with neutral scalars, graphs with pseudoscalars, graphs with both neutral scalars and pseudoscalars and finally graphs with charged scalars: $A = A^h + A^A + A^M + A^C$. The contribution from graphs with only neutral scalars is given by

$$\begin{aligned}
A^h &= \int_0^1 dx \left(-x \log \frac{\beta^h}{\mu^2} + \log \gamma^h \right) (\xi_V^h a_V - \xi_A^h a_A) \\
&\quad + \int dx dy \left[\left(1 + \log \frac{\eta^h}{\mu^2} - \frac{xyk^2}{\eta^h} \right) (\xi_V^h a_V + \xi_A^h a_A) \right. \\
&\quad \left. + \frac{m_t^2(x+y-2)}{\eta^h} (\xi_V^h a_V - \xi_A^h a_A) \right] \\
B^h &= \int_0^1 dx \left(-x \log \frac{\beta^h}{\mu^2} + \log \gamma^h \right) (\xi_V^h a_A - \xi_A^h a_V) \\
&\quad + \int dx dy \left[\left(-1 - \log \frac{\eta^h}{\mu^2} + \frac{xyk^2}{\eta^h} \right) (\xi_V^h a_A + \xi_A^h a_V) \right. \\
&\quad \left. + \frac{m_t^2(x+y-2)}{\eta^h} (\xi_V^h a_A - \xi_A^h a_V) \right] \\
C^h &= m_t^2 \int dx dy \frac{x}{\eta^h} (\xi_V^h a_V - \xi_A^h a_A) + \frac{2y - xy - y^2}{\eta^h} (\xi_V^h a_V + \xi_A^h a_A) \\
D^h &= m_t^2 \int dx dy \frac{x}{\eta^h} (-\xi_V^h a_A + \xi_A^h a_V) + \frac{2y - xy - y^2}{\eta^h} (\xi_V^h a_A + \xi_A^h a_V)
\end{aligned} \tag{A.1}$$

where we have defined the functions

$$\begin{aligned}\beta^h &= (1-x)^2 m_t^2 + x m_h^2 \\ \gamma^h &= \frac{(1-x)m_t^2 + x m_h^2}{(1-x)^2 m_t^2 + x m_h^2} \\ \eta^h &= (1-x-y)m_h^2 + (x+xy+y^2)m_t^2 - xyk^2 + i\epsilon\end{aligned}\tag{A.2}$$

and the couplings

$$a_V^\gamma = \frac{2e}{3}, \quad a_A^\gamma = 0, \quad a_M^\gamma = 0,\tag{A.3}$$

for the photon,

$$a_V^Z = \frac{g}{4 \cos \theta_W} \left(1 - \frac{8}{3} \sin^2 \theta_W\right), \quad a_A^Z = -\frac{g}{4 \cos \theta_W}, \quad a_M^Z = \frac{g}{2 \cos \theta_W}\tag{A.4}$$

for the Z^0 . The products of Yukawa couplings are

$$\xi_V^h = \xi_{tt}(\xi_{ct} + \xi_{tc}^*)/4, \quad \xi_A^h = \xi_{tt}(\xi_{ct} - \xi_{tc}^*)/4\tag{A.5}$$

Finally, k^2 is the mass of the gauge boson and μ is the renormalisation scale. The sum of the graphs is of course finite and the result independent of μ .

The contribution from graphs with only neutral pseudoscalars is given by

$$\begin{aligned}A^A &= \int_0^1 dx \left(-x \log \frac{\beta^A}{\mu^2} - \log \gamma^A \right) (\xi_V^A a_V - \xi_A^A a_A) \\ &\quad + \int dx dy \left[\left(1 + \log \frac{\eta^A}{\mu^2} + \frac{xyk^2}{\eta^A} \right) (\xi_V^A a_V - \xi_A^A a_A) \right. \\ &\quad \left. - \frac{m_t^2(x+y)}{\eta^A} (\xi_V^A a_V + \xi_A^A a_A) \right] \\ B^A &= \int_0^1 dx \left(-x \log \frac{\beta^A}{\mu^2} - \log \gamma^A \right) (\xi_V^A a_A + \xi_A^A a_V) \\ &\quad + \int dx dy \left[\left(-1 - \log \frac{\eta^A}{\mu^2} - \frac{xyk^2}{\eta^A} \right) (\xi_V^A a_A - \xi_A^A a_V) \right. \\ &\quad \left. - \frac{m_t^2(x+y)}{\eta^A} (\xi_V^A a_A + \xi_A^A a_V) \right] \\ C^A &= m_t^2 \int dx dy \frac{-x}{\eta^A} (\xi_V^A a_V + \xi_A^A a_A) - \frac{y(x+y)}{\eta^A} (\xi_V^A a_V - \xi_A^A a_A) \\ D^A &= m_t^2 \int dx dy \frac{x}{\eta^A} (\xi_V^A a_A + \xi_A^A a_V) - \frac{y(x+y)}{\eta^A} (\xi_V^A a_A - \xi_A^A a_V)\end{aligned}\tag{A.6}$$

where

$$\begin{aligned}\beta^A &= (1-x)^2 m_t^2 + x m_A^2 \\ \gamma^A &= \frac{(1-x)m_t^2 + x m_A^2}{(1-x)^2 m_t^2 + x m_A^2} \\ \eta^A &= (1-x-y)m_A^2 + (x+xy+y^2)m_t^2 - xyk^2 + i\epsilon\end{aligned}\tag{A.7}$$

and

$$\xi_V^A = \xi_{tt}(\xi_{ct} - \xi_{tc}^*)/4, \quad \xi_A^A = \xi_{tt}(\xi_{ct} + \xi_{tc}^*)/4.\tag{A.8}$$

The graphs involving both the scalar and pseudoscalar particles give:

$$\begin{aligned}A^M &= a_M \int dx dy \left(\xi_A^{M1} \left(-\log \frac{\eta^{M1}}{\mu^2} + \frac{m_t^2(1-y-xy-x^2)}{\eta^{M1}} \right) \right. \\ &\quad \left. + \xi_A^{M2} \left(\log \frac{\eta^{M2}}{\mu^2} + \frac{m_t^2(1-y+xy-2x+x^2)}{\eta^{M2}} \right) \right) \\ B^M &= a_M \int dx dy \left(\xi_V^{M1} \left(-\log \frac{\eta^{M1}}{\mu^2} + \frac{m_t^2(1-y-xy-x^2)}{\eta^{M1}} \right) \right. \\ &\quad \left. - \xi_V^{M2} \left(\log \frac{\eta^{M2}}{\mu^2} + \frac{m_t^2(1-y+xy-2x+x^2)}{\eta^{M2}} \right) \right) \\ C^M &= a_M m_t^2 \int dx dy \xi_A^{M1} \frac{1-y-xy-x^2}{\eta^{M1}} + \xi_A^{M2} \frac{1-y+xy-2x+x^2}{\eta^{M2}} \\ D^M &= -a_M m_t^2 \int dx dy \xi_V^{M1} \frac{1-y-xy-x^2}{\eta^{M1}} - \xi_V^{M2} \frac{1-y+xy-2x+x^2}{\eta^{M2}}\end{aligned}\tag{A.9}$$

where

$$\begin{aligned}\eta^{M1} &= (1-2x-y+x^2+xy)m_t^2 + x m_h^2 + y m_A^2 - xyk^2 + i\epsilon \\ \eta^{M2} &= (1-2x-y+x^2+xy)m_t^2 + x m_A^2 + y m_h^2 - xyk^2 + i\epsilon\end{aligned}\tag{A.10}$$

and

$$\begin{aligned}\xi_V^{M1} &= \xi_{tt}(\xi_{ct} - \xi_{tc}^*)/4, \quad \xi_A^{M1} = \xi_{tt}(\xi_{ct} + \xi_{tc}^*)/4 \\ \xi_V^{M2} &= \xi_{tt}(\xi_{ct} + \xi_{tc}^*)/4, \quad \xi_A^{M2} = \xi_{tt}(\xi_{ct} - \xi_{tc}^*)/4.\end{aligned}\tag{A.11}$$

Finally, the contribution from graphs involving the charged scalar is

$$\begin{aligned}A^C &= B^C = \xi^C \left[-4a_R \int_0^1 dx x \log \beta^C \right. \\ &\quad \left. + 4b_L \left(\frac{1}{2} + \int dx dy \left[\log \frac{\eta^{C1}}{\mu^2} - \frac{xyk^2}{\eta^{C1}} \right] \right) \right. \\ &\quad \left. + 2j_c \int dx dy \left(\log \frac{\eta^{C2}}{\mu^2} - \frac{m_t^2 y(1-x-y)}{\eta^{C2}} \right) \right] \\ C^C &= -D^C = \xi^C m_t^2 \int dx dy y(1-x-y) \left(\frac{4b_L}{\eta^{C1}} - \frac{2j_c}{\eta^{C2}} \right)\end{aligned}\tag{A.12}$$

where ,

$$\begin{aligned}
\xi^C &= \xi_{tt}\xi_{tc}^*/4 \\
\beta^C &= x(m_{\varphi_2^\pm}^2 - (1-x)m_t^2) \\
\eta^{C1} &= (1-x-y)(m_{\varphi_2^\pm}^2 - xm_t^2) - xyk^2 + i\epsilon \\
\eta^{C2} &= (x+y)m_{\varphi_2^\pm}^2 - y(1-x-y)m_t^2 - xyk^2 + i\epsilon,
\end{aligned} \tag{A.13}$$

and the couplings are

$$a_R^\gamma = \frac{e}{3}, \quad b_L^\gamma = -\frac{e}{6}, \quad j_c^\gamma = e \tag{A.14}$$

for the photon and

$$a_R^Z = -\frac{gs_W^2}{3c_W}, \quad b_L^Z = -\frac{g}{4c_W}(1 - \frac{2}{3}s_W^2), \quad j_c^Z = \frac{g}{2c_W}(1 - 2s_W^2) \tag{A.15}$$

for the Z^0 .
